1. Product Overview

This document mainly describes precautions for using the radar and problems needing attention at each stage, so as to minimize the design cost, and improve the product stability and the project completion efficiency.

This document covers the reference design of hardware circuits, the layout requirements for radar antenna and shell, the way of interference discrimination and multi-functional standard UART protocol output.

This radar is a self-contained distance sensing sensor, which is a module composed of a radio frequency antenna, a radar chip and a high-clock rate MCU. Depending on a stable, flexible and superior algorithm framework core, it intends to satisfy various scene detection needs of users, and supports a master computer or a host computer to flexibly output detection status and data. The number of available GPIO groups can be customized and developed by users.

2. Operating Principle

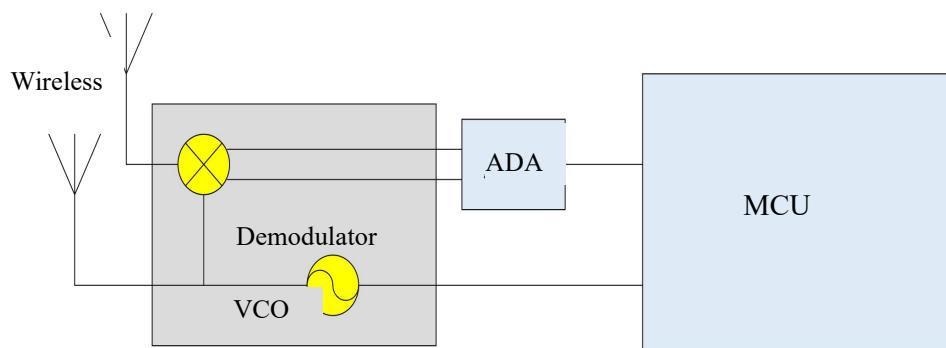

FIG. 1

The radar transmits a 60G band millimeter wave signal, and the detected target reflects an electromagnetic wave signal, which is demodulated according to the transmitted signal, and then processed by amplification, filtering, ADC, etc., to obtain the demodulated echo signal data. The MCU calculates information of amplitude, frequency and phase of the echo signal, and finally achieves measurement of target parameters (e.g., fall, standstill, motion, fine motion) and scene evaluation.

3. Precautions for Hardware Design

The rated power supply voltage of the radar should be 4.9V to 6V. Under normal working conditions, it requires a rated input current of more than 200 mA. For power supply design, the power supply ripple should be not more than 100 mv.

3.1 The power supply can refer to the following circuit designs

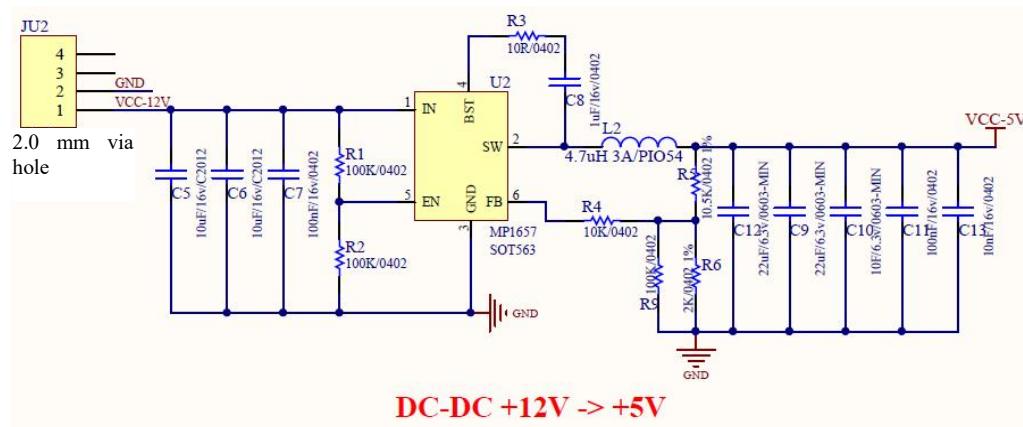

FIG. 2

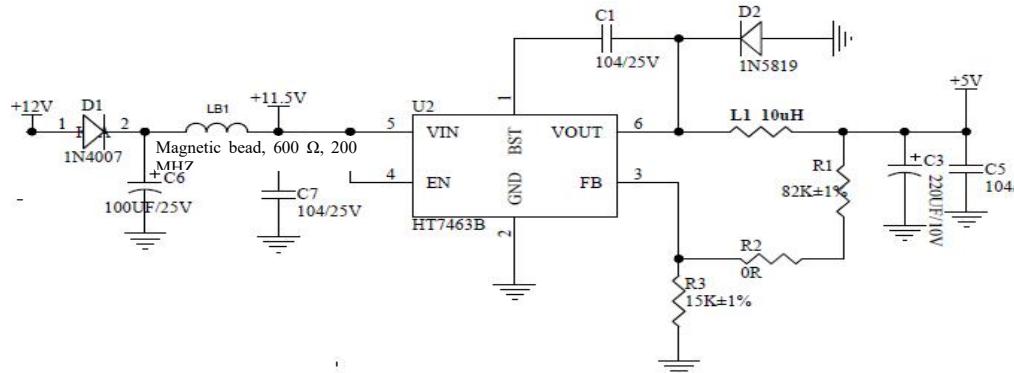

FIG. 3

3.2 Wiring diagram in service

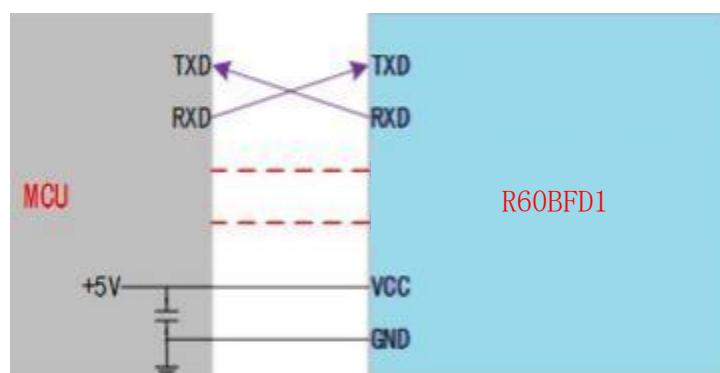

FIG. 4 Wiring schematic diagram of radar module and peripherals

4. Layout Requirements for Antenna and Shell

PCBA: It is necessary to keep the radar at least 1 mm higher than other surface mounting technology (SMT) devices.

Shell structure: it is necessary to keep the radar antenna surface 2 mm to 5 mm away from the shell surface.

Shell detection surface: a non-metallic shell, requiring a flat surface rather than a curve surface that affects the performance of the whole scanning area.

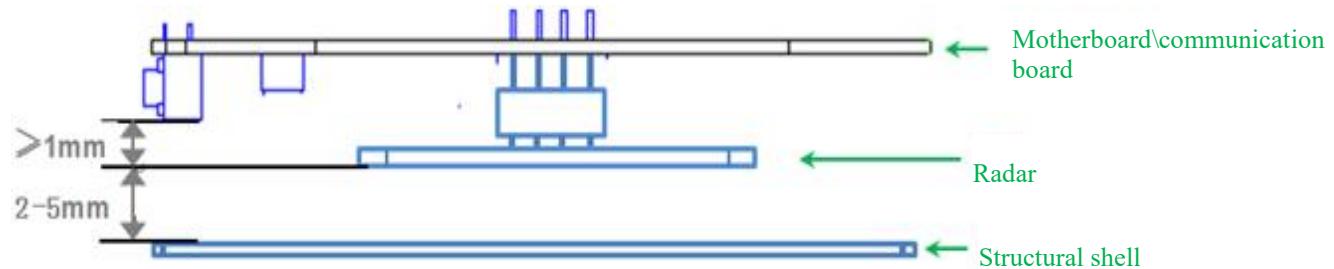

FIG. 5

5. Electrostatic Protection

The radar product has a built-in electrostatic-sensitive circuit, which are vulnerable to electrostatic hazards. Hence, it is necessary to take adequate measures for electrostatic protection during transportation, storage, operation and taking. You cannot touch or grasp the antenna surface and connector pins of the radar module by hand, but only touch the corners.

When operating the radar sensor, please wear anti-static gloves when possible.

6. Functional Details

6.1 Description of function points

Function points	State change time/function explanation
DP1: presence/absence	<p>It reports 0.5 s after detecting a presence state from the previous absence state</p> <p>It outputs an absence state about 30 s after detecting an absence state from the previous presence state</p>
DP2: fall alarm	It sends the alarm immediately in case that the fall alarm condition is met at its discretion.

DP3: standstill alarm	It sends the alarm in case of an abnormal standstill for 5 mins.
DP4: people counting	It detects people in the detection area in real time.

7. Protocol Description

This protocol is applicable to communication between the 60G millimeter-wave fall detection radar and the master computer.

This protocol provides an overview of the radar's work flow, briefly introduces the interface protocol architecture framework, and gives control commands and data necessary for related radar works. The serial communication is defined as follows:

- Interface level: TTL
- Baud rate: 115200 bps
- Stop bit: 1
- Data bit: 8
- Parity check: none

8. Communication Command and Parameter Definition

8.1 Definition and description of frame structure

A. Frame structure definition

Frame	Control field	Command field	Length identifier		Data	Check code	Frame tail
0X53 0X59	Control	Command	Lenth_H	Lenth_H	Data	sum	0X54 0X43
2 Byte	1 Byte	1 Byte	1 Byte	1 Byte	n Byte	1 Byte	2 Byte

B. Description of frame structure

- Frame header: 2 Byte, constant 0X53, 0X59;

- Control field: 1 Byte

(0X01- heartbeat identifier, 0X02- product information, 0X03-OTA upgrade, 0X05- working status, 0X06- installation method, 0X80- presence of human body, 0X83- fall detection)

- Command field: 1 Byte (identifying the current data content)
- Length identifier: 2 Bytes, equal the specific byte length of data
- Data: n Byte, defined based on practical function

- Check code: 1 Byte (check code calculation: frame header + control field + command field + length identifier + data, and take the lower eight bits after summation)
- Frame tail: 2 Byte, constant 0X54, 0X43;

8.2. Description of address assignment and data information

	Finish OTA upgrade	Reply	5359	03	03	0001	0F	sum	5443	

Appendix 1: About Data Instruction Generation Routine

For instance: presence information query:

According to the above protocol table, the data structure for presence information query is confirmed as follows:

- Frame header: 0X53 0X59
- Control field: 0X80
- Command field: 0X81

- Length identifier: 0X00 0X01
- Data: 0X0F
- Check code: 1 Byte (sum)
- Frame tail: 0X54 0X43
- Combined into a complete instruction as follows: 53 59 80 81 00 01 0F sum 54 43
- Check code sum: (0X53+0X59+0X80+0X81+0X00+0X01+0X0F) = 0X01BD
- Take low byte to obtain sum = 0XBD
- Therefore, the complete presence information query instruction is: 53 59 80 81 00 01 0F BD 54 43
